#### Abstract

We consider a wide class of quadratic optimization problems with integer and Boolean variables. In this paper, the lower and upper bounds on the strong stability radius of the set of extremum solutions are obtained in the situation where solution space and criterion space are endowed with various Hölder's norms.

Keywords: Boolean programming, quadratic problem, multicriteria optimization, Pareto set, stability radius, Hölder's norms

## 1 Problem formulation and basic definitions

Let $A=\left[a_{i j k}\right]$ be a $n \times n \times m$ - matrix with corresponding cuts $A_{k} \in \mathbf{R}^{n \times n}, k \in$ $N_{m}=\{1,2, \ldots, m\}, m \geq 1$. Let $X \subseteq \mathbf{Z}^{n}, 2 \leq|X|<\infty$, be a set of feasible solutions (integer vectors) $x=\left(x_{1}, x_{2}, \ldots, x_{n}\right)^{T}, n \geq 2$.

We define a vector criterion

$$
f(x, A)=\left(f_{1}\left(x, A_{1}\right), f_{2}\left(x, A_{2}\right), \ldots, f_{m}\left(x, A_{m}\right)\right) \rightarrow \min _{x \in X}
$$

with partial criteria being quadratic functions

$$
f_{k}\left(x, A_{k}\right)=x^{T} A_{k} x, k \in N_{m}
$$

In decision making theory, along with the well-known Pareto optimality principle (see e.g. [1]), various choice functions are considered [2-5]. In this paper, under $m$-criteria quadratic problem $Z_{m}(A)$ we understand the problem of finding the set of extremum solutions defined in traditional way (see e.g. [2-4]):

$$
C_{m}(A)=\left\{x \in X: \exists s \in N_{m} \forall x^{\prime} \in X \quad\left(g_{s}\left(x, x^{\prime}, A_{s}\right) \leq 0\right)\right\}
$$

where

$$
g_{s}\left(x, x^{\prime}, A_{s}\right)=f_{s}\left(x, A_{s}\right)-f_{s}\left(x^{\prime}, A_{s}\right)=\left(x-x^{\prime}\right)^{T} A_{s}\left(x-x^{\prime}\right)
$$

Thus, the choice of extremum solutions can be interpreted as finding best solutions for each of $m$ criteria, and then combining them into one set. In other words, the set of extremum solutions contains all the individual minimizers of each objective. Obviously, $C_{1}(A), A \in \mathbf{R}^{n \times n}$ is the set of optimal solutions for scalar problem $Z_{1}(A)$ with $A \in \mathbf{R}^{n \times n}$.

Taking into account that $X$ is finite, the following formulae below are true:

$$
\left.\begin{array}{rl}
C_{m}(A)=S_{m}(A) \backslash & \left(P_{m}(A) \backslash L_{m}(A)\right)
\end{array}\right) L_{m}(A) \cup\left(S_{m}(A) \backslash P_{m}(A)\right), ~ 子 \begin{aligned}
& C_{m}(A) \cap P_{m}(A)=L_{m}(A), \\
& L_{m}(A) \subseteq P_{m}(A) \subseteq S_{m}(A), \\
& L_{m}(A) \subseteq C_{m}(A) \subseteq S_{m}(A),
\end{aligned}
$$

where $P_{m}(A)$ denotes the Pareto set [6], $S_{m}(A)$ denotes the Slater set [7], and $L_{m}(A)$ denotes the lexicographic set (see e.g. $[1,8]$ ). Below we define all the three sets in a traditional way see e.g. [9-11]:

$$
\begin{gathered}
P_{m}(A)=\{x \in X: X(x, A)=\emptyset\} \\
S_{m}(A)=\left\{x \in X: \nexists x^{0} \in X \forall k \in N_{m}\left(g_{k}\left(x, x^{0}, A_{k}\right)>0\right)\right\} \\
L_{m}(A)=\bigcup_{\pi \in \Pi_{m}} L(A, \pi) \\
L(A, \pi)=\left\{x \in X: \forall x^{\prime} \in X \quad\left(g\left(x, x^{\prime}, A\right) \leq_{\pi} 0_{(m)}\right)\right\}
\end{gathered}
$$

$$
\begin{gathered}
X(x, A)=\left\{x^{\prime} \in X: g\left(x, x^{\prime}, A\right) \geq 0_{(m)} \& g\left(x, x^{\prime}, A\right) \neq 0_{(m)}\right\} \\
g\left(x, x^{\prime}, A\right)=\left(g_{1}\left(x, x^{\prime}, A_{1}\right), g_{2}\left(x, x^{\prime}, A_{2}\right), \ldots, g_{m}\left(x, x^{\prime}, A_{m}\right)\right) \\
0_{(m)}=(0,0, \ldots, 0) \in \mathbf{R}^{m}
\end{gathered}
$$

Here $\Pi_{m}$ is the set of all $m$ ! permutations of numbers $1,2, \ldots, m ; \pi=\left(\pi_{1}, \pi_{2}, \ldots, \pi_{m}\right) \in$ $\Pi_{m}$; and the binary relation of lexicographic order between two vectors $y=$ $\left(y_{1}, y_{2}, \ldots, y_{m}\right) \in \mathbf{R}^{m}$ and $y^{\prime}=\left(y_{1}^{\prime}, y_{2}^{\prime}, \ldots, y_{m}^{\prime}\right) \in \mathbf{R}^{m}$ is defined as follows

$$
\begin{gathered}
y \leq \pi y^{\prime} \Longleftrightarrow \\
\left(y=y^{\prime}\right) \vee\left(\exists k \in N_{m} \forall i \in N_{k-1}\left(y_{\pi_{k}}<y_{\pi_{k}}^{\prime} \& y_{\pi_{i}}=y_{\pi_{i}}^{\prime}\right)\right)
\end{gathered}
$$

where $N_{0}=\emptyset$. Obviously all the sets, $P_{m}(A), S_{m}(A), L_{m}(A)$ and $C_{m}(A)$, are non-empty for any matrix $A=\left[a_{i j k}\right] \in \mathbf{R}^{n \times n \times m}$ due to the finite number of alternatives in $X$.

We will perturb the elements of matrix $A \in \mathbf{R}^{n \times n \times m}$ by adding elements of the perturbing matrix $A^{\prime} \in \mathbf{R}^{n \times n \times m}$. Thus the perturbed problem $Z_{m}\left(A+A^{\prime}\right)$ of finding extremum solutions has the following form

$$
f\left(x, A+A^{\prime}\right) \rightarrow \min _{x \in X}
$$

In the solution space $\mathbf{R}^{n}$, we define an arbitrary Hölder's norm $l_{p}, p \in[1, \infty]$, i.e. under norm of vector $a=\left(a_{1}, a_{2}, \ldots, a_{n}\right)^{T} \in \mathbf{R}^{n}$ we understand the number

$$
\|a\|_{p}= \begin{cases}\left(\sum_{j \in N_{n}}\left|a_{j}\right|^{p}\right)^{1 / p} & \text { if } 1 \leq p<\infty \\ \max \left\{\left|a_{j}\right|: j \in N_{n}\right\} & \text { if } p=\infty\end{cases}
$$

Thus, for any matrix $A_{k} \in \mathbf{R}^{n \times n}$, the norm of the matrix is defined as a norm of vector composed of all the matrix elements.

In the criterion space $\mathbf{R}^{m}$, we define another Hölder's norm $l_{q}, q \in[1, \infty]$, i.e. under norm of matrix $A \in \mathbf{R}^{n \times n \times m}$ we understand the number

$$
\|A\|_{p q}=\left\|\left(\left\|A_{1}\right\|_{p},\left\|A_{2}\right\|_{p}, \ldots,\left\|A_{m}\right\|_{p}\right)\right\|_{q}
$$

It is easy to see that

$$
\begin{equation*}
\left\|A_{k}\right\|_{p} \leq\|A\|_{p q}, k \in N_{m} \tag{1}
\end{equation*}
$$

Let $\zeta$ be either $p$ or $q$. It is well-known that $l_{\zeta}$ norm, defined in $\mathbf{R}^{n}$, induces conjugated $l_{\zeta^{*}}$ norm in $\left(\mathbf{R}^{n}\right)^{*}$. For $\zeta$ and $\zeta^{*}$, the following relations hold

$$
\frac{1}{\zeta}+\frac{1}{\zeta^{*}}=1, \quad 1<\zeta<\infty
$$

In addition, if $\zeta=1$ then $\zeta^{*}=\infty$. Obviously, if $\zeta^{*}=1$ then $\zeta=\infty$. Also notice that $\zeta$ and $\zeta^{*}$ belong to the same range $[1, \infty]$. We also set $\frac{1}{\zeta}=0$ if $\zeta=\infty$.

For any two vectors $a$ and $b$ of the same dimension, the following Hölder's inequalities are well-known (see e.g. [12])

$$
\begin{equation*}
\left|a^{T} b\right| \leq\|a\|_{\zeta}\|b\|_{\zeta^{*}} \tag{2}
\end{equation*}
$$

To any vector $x=\left(x_{1}, x_{2}, \ldots, x_{n}\right)^{T} \in \mathbf{Z}^{n}$, we assign a vector $\tilde{x}$ composed of all the possible products $x_{i} x_{j}$, i.e.

$$
\tilde{x}=\left(x_{1} x_{1}, x_{1} x_{2}, \ldots, x_{n} x_{n-1}, x_{n} x_{n}\right)^{T} \in \mathbf{Z}^{n^{2}}
$$

Taking into account Hölder's inequalities (2), we can see that for any $x, x^{\prime} \in$ $\mathbf{Z}^{n}$ and $k \in N_{m}$ the following inequalities hold

$$
\begin{gather*}
\left|f_{k}\left(x, A_{k}\right)\right|=\left|x^{T} A_{k} x\right|=\left|A_{k} x x^{T}\right| \leq\left\|A_{k}\right\|_{p}\|\tilde{x}\|_{p^{*}} \\
\left|g_{k}\left(x, x^{\prime}, A_{k}\right)\right| \leq\left\|A_{k}\right\|_{p}\left\|\tilde{x}-\tilde{x^{\prime}}\right\|_{p^{*}} \tag{3}
\end{gather*}
$$

It is also easy to see that for any vector $a=\left(a_{1}, a_{2}, \ldots, a_{n}\right)^{T} \in \mathbf{R}^{n}$ with condition $\left|a_{j}\right|=\alpha, j \in N_{n}$, and any matrix $A_{k}=\left[a_{i j k}\right] \in \mathbf{R}^{n \times n}$ with condition $\left|a_{i j k}\right|=\alpha,(i, j) \in N_{n} \times N_{n}$, the following inequalities are valid

$$
\begin{gather*}
\|a\|_{p}=\alpha n^{\frac{1}{p}}  \tag{4}\\
\left\|A_{k}\right\|_{p}=\alpha n^{\frac{2}{p}} \tag{5}
\end{gather*}
$$

Given $\varepsilon>0$, let

$$
\Omega_{p q}(\varepsilon)=\left\{A^{\prime} \in \mathbf{R}^{n \times n \times m}:\left\|A^{\prime}\right\|_{p q}<\varepsilon\right\}
$$

be the set of perturbing matrices $A^{\prime}$ with cuts $A_{k}^{\prime} \in \mathbf{R}^{n \times n}, k \in N_{m}$, and $\left\|A^{\prime}\right\|_{p q}$ is the norm of $A^{\prime}=\left[a_{i j k}^{\prime}\right] \in \mathbf{R}^{n \times n \times m}$. Denote

$$
\Xi_{p q}=\left\{\varepsilon>0: \quad \forall A^{\prime} \in \Omega_{p q}(\varepsilon)\left(C_{m}\left(A+A^{\prime}\right) \cap C_{m}(A) \neq \emptyset\right)\right\}
$$

Following [10] and [13], the number

$$
\rho_{m}(p, q)= \begin{cases}\sup \Xi_{p q} & \text { if } \Xi_{p q} \neq \emptyset \\ 0 & \text { if } \Xi_{p q}=\emptyset\end{cases}
$$

is called the strong stability (in terminology of [14] and [15] $T_{1}$-stability) radius of problem $Z_{m}(A), m \in \mathbf{N}$, with Hölder's norms $l_{p}$ and $l_{q}$ in the spaces $\mathbf{R}^{n}$ and $\mathbf{R}^{m}$ respectively. Thus, the strong stability radius of problem $Z_{m}(A)$ defines the extreme level of independent perturbations of the elements of matrix $A$ in the space $\mathbf{R}^{n \times n \times m}$ not leading to the situation where new extremum solutions appear.

## 2 Main result

Given $p, q \in[1, \infty]$, for problem $Z_{m}(A), m \in \mathbf{N}$, we set

$$
\begin{gathered}
\phi_{m}(p)=\min _{x \notin C_{m}(A)} \min _{k \in N_{m}} \max _{x^{\prime} \in X \backslash\{x\}} \frac{g_{k}\left(x, x^{\prime}, A_{k}\right)}{\left\|\tilde{x}-\tilde{x^{\prime}}\right\|_{p^{*}}}, \\
\psi_{m}(p)=\max _{x^{\prime} \in C_{m}(A)} \max _{k \in N_{m}} \min _{x \notin C_{m}(A)} \frac{g_{k}\left(x, x^{\prime}, A_{k}\right)}{\left\|\tilde{x}-\tilde{x^{\prime}}\right\|_{p^{*}}}, \\
\gamma_{m}(p, q)=n^{\frac{2}{p}} m^{\frac{1}{q}} \min _{x \notin C_{m}(A)} \max _{k \in N_{m}} \max _{x^{\prime} \in C_{m}(A)} \frac{g_{k}\left(x, x^{\prime}, A_{k}\right)}{\left\|\tilde{x}-\tilde{x^{\prime}}\right\|_{1}} .
\end{gathered}
$$

It is evident that if $C_{m}(A)=X$, the inequality

$$
C_{m}\left(A+A^{\prime}\right) \cap C_{m}(A) \neq \emptyset
$$

holds for any perturbing matrix $A^{\prime} \in \Omega_{p q}(\varepsilon)$ with $\varepsilon>0$. So, the stability radius is infinite when $C_{m}(A)=X$. The problem $Z_{m}(A)$ that satisfies $C_{m}(A) \neq X$ is called non-trivial.

Theorem 1 Given $p, q \in[1, \infty]$ and $m \in \mathbf{N}$, for the strong stability radius $\rho_{m}(p, q)$ of non-trivial problem $Z_{m}(A)$, the following lower bound is valid

$$
\rho_{m}(p, q) \geq \max \left\{\phi_{m}(p), \psi_{m}(p)\right\}>0
$$

In addition,

$$
\begin{equation*}
\gamma_{m}(p, q) \geq \rho_{m}(p, q) \geq \max \left\{\phi_{m}(p), \psi_{m}(p)\right\}>0 \tag{6}
\end{equation*}
$$

if $Z^{m}(A)$ is a problem with Boolean variables, i.e. if $X \subseteq \mathbf{E}^{n}$.
Proof. Since the formula

$$
\forall x \notin C_{m}(A) \quad \forall k \in N_{m} \exists x^{0} \in X \quad\left(g_{k}\left(x, x^{0}, A_{k}\right)>0\right)
$$

is true, the inequality $\phi_{m}(p)>0$ tells us that the lower bound on the strong stability radius as well as the strong stability radius itself are always positive.

First, we prove that $\rho_{m}(p, q) \geq \phi_{m}(p)$. Let $A^{\prime} \in \Omega_{p q}\left(\phi_{m}(p)\right)$ be a perturbing matrix with cuts $A_{k}^{\prime} \in \mathbf{R}^{n \times n}, k \in N_{m}$. Then according to the definition of the number $\phi_{m}(p)$, for any index $k \in N_{m}$ and any solution $x \notin C_{m}(A)$ there exists a solution $x^{0} \in X \backslash\{x\}$ such that

$$
\frac{g_{k}\left(x, x^{0}, A_{k}\right)}{\left\|\tilde{x}-\tilde{x^{0}}\right\|_{p^{*}}} \geq \phi_{m}(p)>\left\|A^{\prime}\right\|_{p q} \geq\left\|A_{k}^{\prime}\right\|_{p}
$$

due to (1). Using (3) we conclude that for any $k \in N_{m}$ there exists $x^{0} \neq x$ such that

$$
\begin{gathered}
g_{k}\left(x, x^{0}, A_{k}+A_{k}^{\prime}\right)=g_{k}\left(x, x^{0}, A_{k}\right)+g_{k}\left(x, x^{0}, A_{k}^{\prime}\right) \geq \\
g_{k}\left(x, x^{0}, A_{k}\right)-\left\|A_{k}^{\prime}\right\|_{p}\left\|\tilde{x}-\tilde{x^{0}}\right\|_{p^{*}}>0,
\end{gathered}
$$

i.e. $x \notin C_{m}\left(A+A^{\prime}\right)$, Thus, any solution that is not extremum in the problem $Z_{m}(A)$ so stays in the problem $Z_{m}\left(A+A^{\prime}\right)$. Then we conclude that for any perturbing matrix $A^{\prime} \in \Omega_{p q}\left(\phi_{m}(p)\right)$ the inclusion holds $\emptyset \neq C_{m}\left(A+A^{\prime}\right) \subseteq$ $C_{m}(A)$. It implies that $C_{m}\left(A+A^{\prime}\right) \cap C_{m}(A) \neq \emptyset$ for any $A^{\prime} \in \Omega_{p q}\left(\phi_{m}(p)\right)$, and hence $\rho_{m}(p, q) \geq \phi_{m}(p)$.

Further, we prove that $\rho_{m}(p, q) \geq \psi_{m}(p)$. Since the formula

$$
\exists x^{\prime} \in C_{m}(A) \quad \exists k \in N_{m} \forall x \notin C_{m}(A) \quad\left(C_{k}\left(x-x^{\prime}\right)>0\right)
$$

is true, the inequality $\psi_{m}(p)>0$ is also evident.
Let $A^{\prime} \in \Omega_{p q}\left(\psi_{m}(p)\right)$ be a perturbing matrix with cuts $A_{k}^{\prime} \in \mathbf{R}^{n \times n}, k \in N_{m}$. Then according to the definition of the number $\psi_{m}(p)$, there exist index $s \in N_{m}$ and solution $x^{0} \in C_{m}(A)$ such that for any solution $x \notin C_{m}(A)$ we have

$$
\frac{g_{s}\left(x, x^{0}, A_{s}\right)}{\left\|\tilde{x}-\tilde{x}^{0}\right\|_{p^{*}}} \geq \psi_{m}(p)>\left\|A^{\prime}\right\|_{p q} \geq\left\|A_{s}^{\prime}\right\|_{p}
$$

due to (1). Using (3), we conclude that for any $x \notin C_{m}(A)$ and any $A^{\prime} \in$ $\Omega_{p q}\left(\psi_{m}(p)\right)$ the following inequalities hold

$$
\begin{gathered}
g_{s}\left(x, x^{0}, A_{s}+A_{s}^{\prime}\right)=g_{s}\left(x, x^{0}, A_{s}\right)+g_{s}\left(x, x^{0}, A_{s}^{\prime}\right) \geq \\
g_{s}\left(x, x^{0}, A_{k}\right)-\left\|A_{s}^{\prime}\right\|_{p}\left\|\tilde{x}-\tilde{x^{0}}\right\|_{p^{*}}>0 .
\end{gathered}
$$

Therefore,

$$
\left(X \backslash C_{m}(A)\right) \cap C_{s}\left(x^{0}, A_{s}+A_{s}^{\prime}\right)=\emptyset,
$$

where

$$
C_{s}\left(x^{0}, A_{s}+A_{s}^{\prime}\right)=\left\{x \in X: g_{s}\left(x^{0}, x, A_{s}+A_{s}^{\prime}\right)>0\right\} .
$$

Thus, any solution that is not extremum in the problem $Z_{m}(A)$ so stays in the problem $Z_{m}\left(A+A^{\prime}\right)$. Then we conclude that for any perturbing matrix $A^{\prime} \in$ $\Omega_{p q}\left(\psi_{m}(p)\right)$ the following inequality holds

$$
C_{m}\left(A+A^{\prime}\right) \cap C_{m}(A) \neq \emptyset,
$$

and hence $\rho_{m}(p, q) \geq \psi_{m}(p)$.
Further we will consider the problem $Z_{m}(A)$ with Boolean variables ( $X \subseteq$ $\left.\mathbf{E}^{n}\right)$. And we demonstrate that $\gamma_{m}(p, q) \geq \rho_{m}(p, q)$. According to the definition of number $\gamma_{m}(p, q)$, there exists a Boolean solution $x^{0}=\left(x_{1}^{0}, x_{2}^{0}, \ldots, x_{n}^{0}\right) \notin C_{m}(A)$, $x^{0} \in \mathbf{E}^{n}$ such that for any extremum solution $x \in C_{m}(A)$ and any index $k \in N_{m}$ we get

$$
\begin{equation*}
\gamma_{m}(p, q)\left\|\tilde{x^{0}}-\tilde{x}\right\|_{1} \geq n^{\frac{2}{p}} m^{\frac{1}{q}} g_{k}\left(x^{0}, x, A_{k}\right) \tag{7}
\end{equation*}
$$

Setting $\varepsilon>\gamma_{m}(p, q)$, we define the elements $a_{i j k}^{0}$ of any cut $A_{k}^{0}, k \in N_{m}$, of the perturbing matrix $A^{0}$ according to the formula

$$
a_{i j k}^{0}= \begin{cases}-\delta & \text { if } x_{i}^{0} x_{j}^{0}=1 \\ \delta & \text { if } x_{i}^{0} x_{j}^{0}=0\end{cases}
$$

where

$$
\begin{equation*}
\gamma_{m}(p, q)<\delta n^{\frac{2}{p}} m^{\frac{1}{q}}<\varepsilon \tag{8}
\end{equation*}
$$

Then according to (4) and (5), we get

$$
\begin{gathered}
\left\|A_{s}^{0}\right\|_{p}=\delta n^{\frac{2}{p}} \\
\left\|A^{0}\right\|_{p q}=\delta n^{\frac{2}{p}} m^{\frac{1}{q}} \\
A^{0} \in \Omega_{p q}(\varepsilon)
\end{gathered}
$$

In addition, due to the construction of matrix $A_{k}^{0}$, for any solution $x \neq x^{0}$ we have

$$
\begin{gather*}
g_{k}\left(x^{0}, x, A_{k}^{0}\right)=\left(x^{0}-x\right)^{T} A_{k}^{0}\left(x^{0}-x\right)= \\
\sum_{i \in N_{n}} \sum_{j \in N_{n}} a_{i j k}^{0}\left(x_{i}^{0} x_{j}^{0}-x_{i} x_{j}\right)=-\delta\left\|\tilde{x^{0}}-\tilde{x}\right\|_{1} \tag{9}
\end{gather*}
$$

Using (7), (8) and (9), we continue

$$
\begin{gathered}
g_{k}\left(x^{0}, x, A_{k}+A_{k}^{0}\right)=g_{k}\left(x^{0}, x, A_{k}\right)+g_{k}\left(x^{0}, x, A_{k}^{0}\right) \leq \\
\left(\gamma_{m}(p, q)\left(n^{\frac{2}{p}} m^{\frac{1}{q}}\right)^{-1}-\delta\right)\left\|x^{0}-\tilde{x}\right\|_{1}<0 .
\end{gathered}
$$

Thus, $x \notin C_{m}\left(A+A^{0}\right)$ when $x \in C_{m}(A)$. Summarizing, for any $\varepsilon>\gamma_{m}(p, q)$, we can guarantee the existence of the perturbing matrix $A^{0} \in \Omega_{p q}(\varepsilon)$ such that

$$
C_{m}\left(A+A^{0}\right) \cap C_{m}(A)=\emptyset
$$

i.e. $\rho_{m}(p . q)<\varepsilon$ for any number $\varepsilon>\gamma_{m}(p, q)$. So, inequality (6) holds. The Theorem has been proven.

From the Theorem we get the following result.
Corollary 1 If $Z_{m}(A), A \in \mathbf{R}^{m \times n}$, is a non-trivial problem with Boolean variables, i.e. if $C_{m}(A) \neq X \subseteq \mathbf{E}^{n}$, then for any $m \in \mathbf{N}$.

$$
0<\max \{\phi, \psi\} \leq \rho_{m}(\infty, \infty) \leq \gamma
$$

where

$$
\begin{aligned}
& \phi=\min _{x \notin C_{m}(A)} \min _{k \in N_{m}} \max _{x^{\prime} \in X \backslash\{x\}} \frac{g_{k}\left(x, x^{\prime}, A_{k}\right)}{\| \tilde{x}-\tilde{x^{\prime} \|_{1}}} \\
& \psi=\max _{x^{\prime} \in C_{m}(A)} \max _{k \in N_{m}} \min _{x \notin C_{m}(A)} \frac{g_{k}\left(x, x^{\prime}, A_{k}\right)}{\| \tilde{x}-\tilde{x^{\prime} \|_{1}}} \\
& \gamma=\min _{x \notin C_{m}(A)} \max _{k \in N_{m}} \max _{x^{\prime} \in C_{m}(A)} \frac{g_{k}\left(x, x^{\prime}, A_{k}\right)}{\| \tilde{x}-\tilde{x^{\prime} \|_{1}}}
\end{aligned}
$$

Corollary 2 If $Z_{1}(A), A \in \mathbf{R}^{n}$, is a scalar non-trivial problem with Boolean variables ( $X \subseteq \mathbf{E}^{n}$ ), then the following formula holds

$$
\rho_{1}(\infty, q)=\min _{x \notin C_{1}(A)} \max _{x^{\prime} \in X \backslash\{x\}} \frac{g\left(x, x^{\prime}, A\right)}{\| \tilde{x}-\tilde{x^{\prime} \|_{1}}}
$$

Finally, we notice that Corollary 2 proves the attainability of $\phi_{m}(\rho)$ and $\gamma_{m}(p, q)$ when $m=1$ and $p=\infty$.
